Common solid state battery chemistries

Characteristics

- Medium to high energy density
- Limited cycle life (<1000)
- Large packaging overhead

Lead-acid battery:

$$E_{oc} = 2.05 \text{ V}$$

NiMH battery:

$$E_{oc} = 1.28 \text{ V}$$

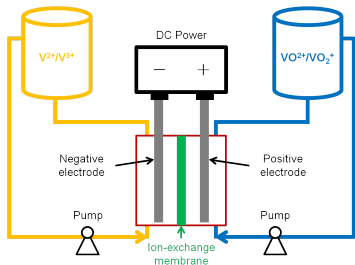

Li-ion battery:

$$E_{oc} = 4.00 \text{ V}$$

Characteristics

- Low packaging overhead
- Unlimited cycle life
- Low energy density

Vanadium:

Cathode:

$$E_{oc} = 1.26 \text{ V}$$

Anode:

Zinc-Bromine:

Cathode:

$$E_{oc} = 1.67 \text{ V}$$

Anode:

The advantages of solid state and flow batteries could be combined?

The advantages of solid state and flow batteries could be combined?

The range of an electric vehicle could be extended to 500 or even 1000 miles?

The advantages of solid state and flow batteries could be combined?

The range of an electric vehicle could be extended to 500 or even 1000 miles?

Refueling stations could replace spent energy storage media and provide a full charge in a few minutes?

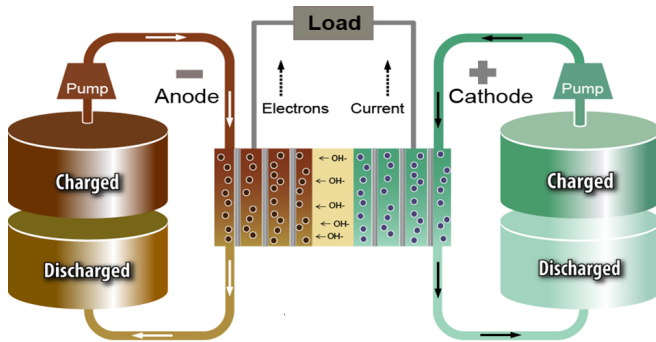

The advantages of solid state and flow batteries could be combined?

The range of an electric vehicle could be extended to 500 or even 1000 miles?

Refueling stations could replace spent energy storage media and provide a full charge in a few minutes?

This is the original idea behind Nanoelectrofuel!

Nanoelectrofuel flow battery

Suspended electroactive nanoparticles

Advantages of flow batteries

Energy density of solid state

Chemistry agnostic

aqueous or non-aqueous

Initial ~~arpa~~ funding

IIT/Argonne collaboration

Prototype: 1 kWh total energy stored
40 V, C/3 discharge rate

Develop commercialization plan

Advantages of nanoelectrofuel

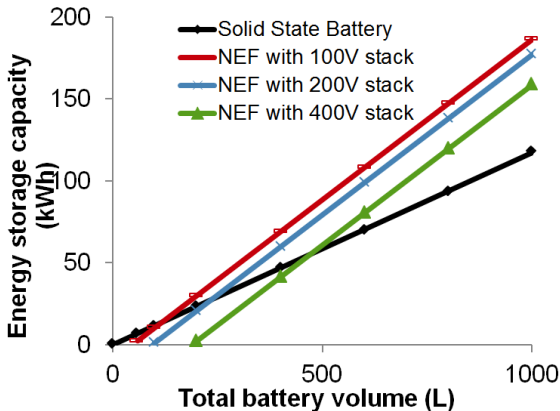

of active material
in solid batteries

of active material
in NEF flow batteries

initial overhead for
power stack depends on
desired voltage

active material fraction
depends on loading
(50% shown)

in NEF flow batteries

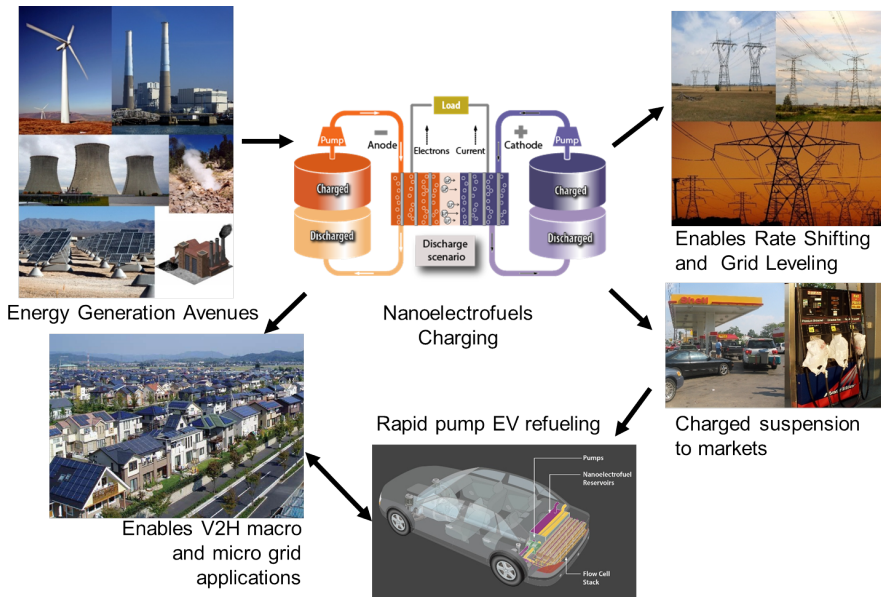

initial overhead for
power stack depends on
desired voltage

active material fraction
depends on loading
(50% shown)

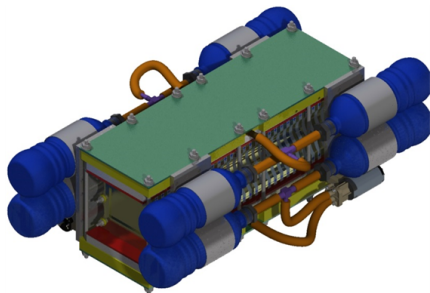

beyond 50 kWh, NEF
has higher volumetric ca-
pacity

Long term vision

- What is the intrinsic performance of active materials in nanoparticle form?
- Can suspended nanoparticles be effectively charged and discharged during flow?
- How much loading can be stabilized in suspension?
- Will these nanoelectrofuels be pumpable and not destroy the enclosure materials?
- Can the technology be economical enough to compete with more established technologies?

40 V aqueous chemistry stack

25 kWh using 4.5 L of nanoelectrofuel

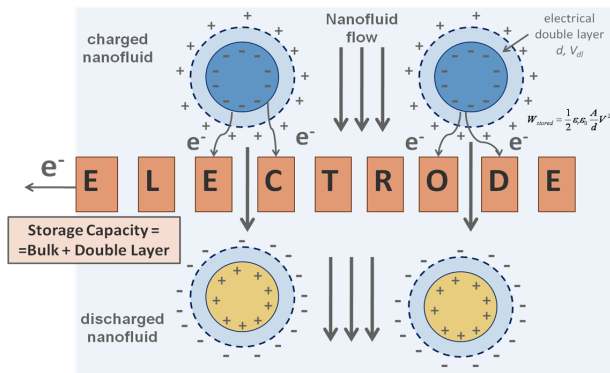

26 kg stack, 10 kg 50% loaded fluid

70 Wh/kg (compare to 40 Wh/kg for Pb-acid)

Charging & discharging nanoelectrofuel

Charging and discharging in a flow can be achieved by proper design of the electrode but all these ideas have to be validated through computation and experiment.

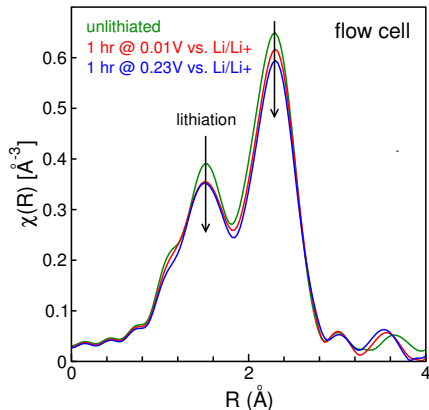

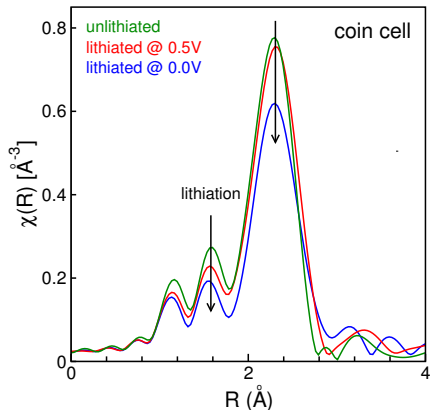

- Porous electrode for high contact probability
- Turbulent flow to maximize electrode contact
- Moderate pressure drop across the cell
- Must have electron transfer with transient contact

First charging results

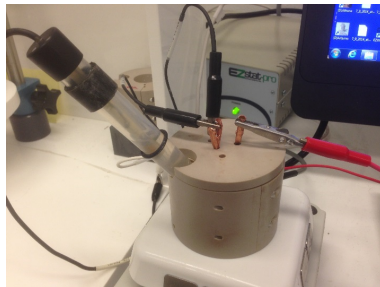

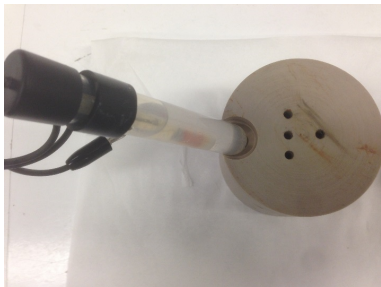

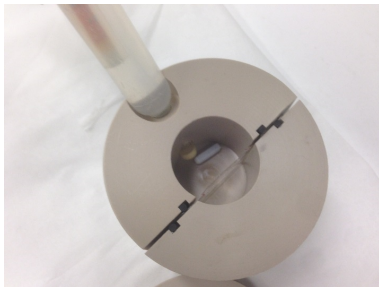

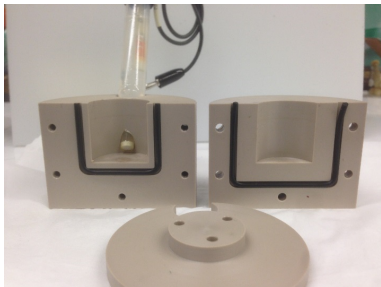

December 2012 data comparing x-ray absorption spectroscopy results on Cu_6Sn_5 anode material in a coin cell and flowing through a metal frit.

Similar trends indicate that nanoparticles in the flow cell are charging, albeit slowly and inefficiently.

Beaker cell for initial charging tests

Initial nanofluid charging using a beaker cell

Agitation using a magnetic stir bar with a wire mesh current collector immersed in fluid

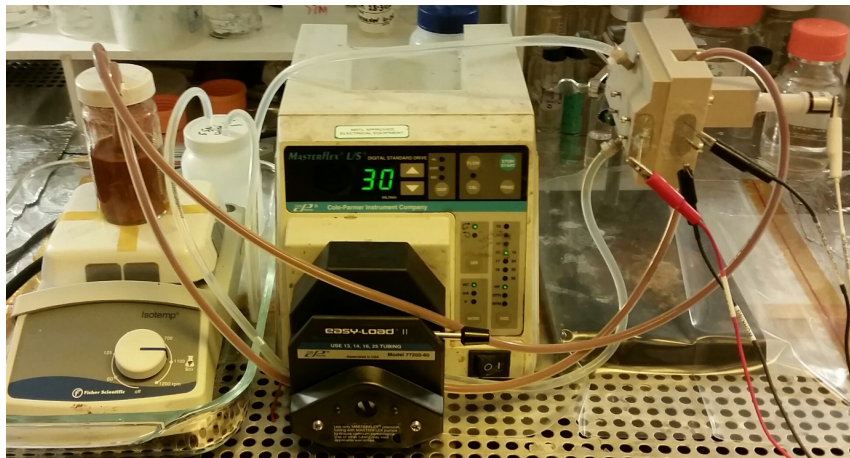

Non-aqueous (Li-ion) chemistries have very low conductivity and require significant research to move forward

Aqueous chemistries easier to charge and more compatible with “real” world

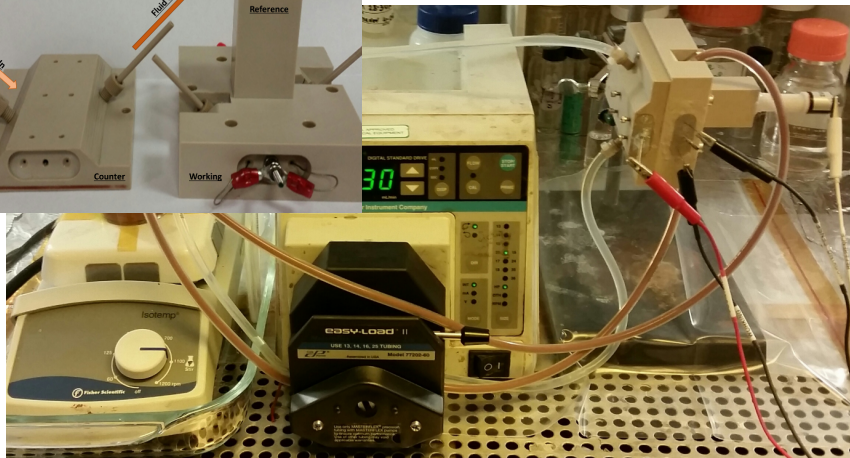

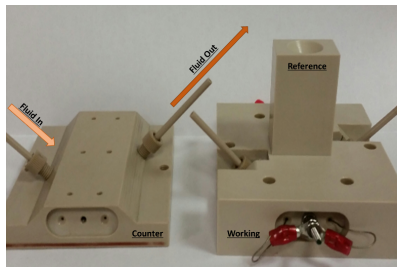

Charge/discharge times still $10\times$ too slow!

Need a flow-through system to improve charge/discharge times

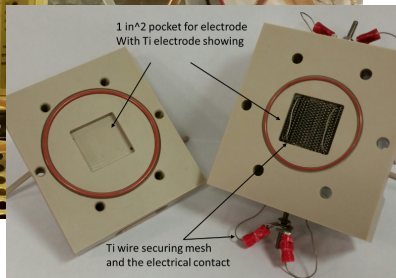

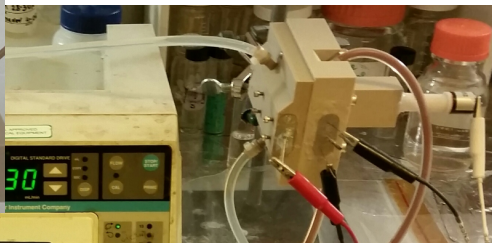

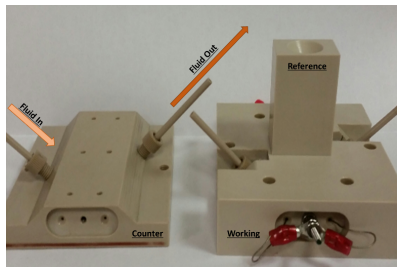

Test flow cell

Test flow cell

Test flow cell

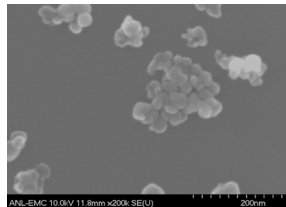

NEF anode: Fe_2O_3

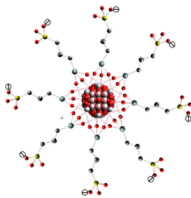

Start with commercially available Fe_2O_3 suspended in water with $\sim 5\text{M}$ LiOH

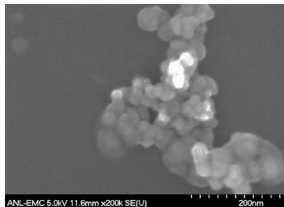

The goal is to reduce Fe^{+3} to Fe^{+2} and there are three reactions present which compete with each other

pristine Fe_2O_3

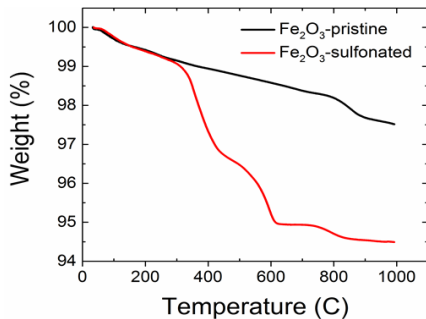

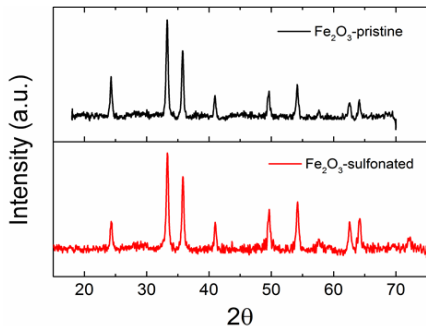

treat with $\sim 3 \text{ wt}\%$
 $(\text{OH})_3\text{--Si--}(\text{CH}_3)_3\text{--SO}_3$

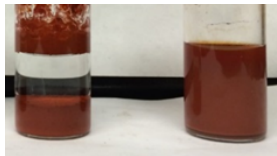

sulfonated Fe_2O_3

Fe₂O₃ nanoparticle characterization

X-ray diffraction shows no structural changes with sulfonation

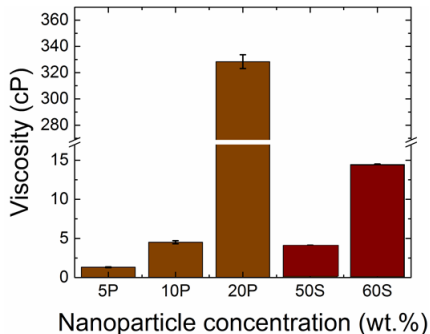

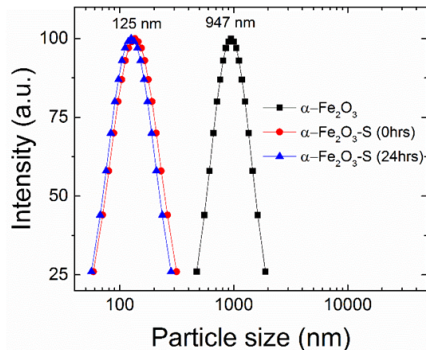

TGA measurement shows ~3 wt% due to surface treatment, about 1 monolayer on a typical nanoparticle

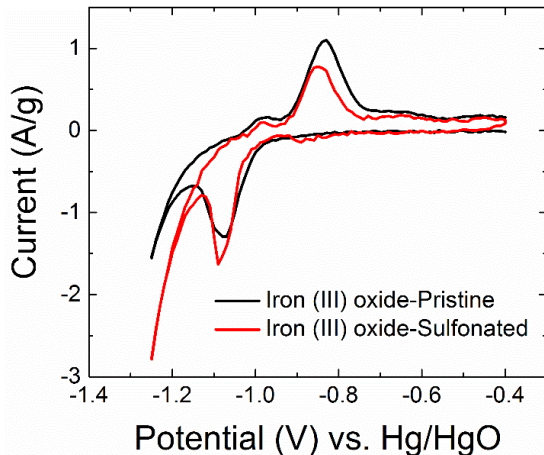

5 wt% pristine (left) vs. modified (right) nanofluid after 2 weeks

Dynamic light scattering measurements of Fe₂O₃ nanofluids

Viscosity comparison of pristine (P) and modified (S) Fe₂O₃ nanofluids

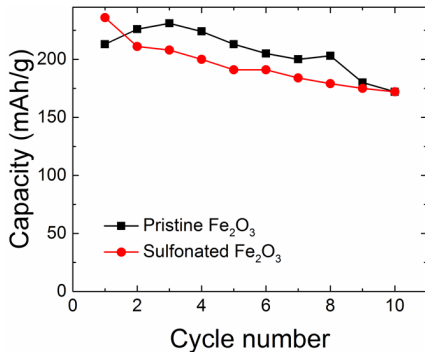

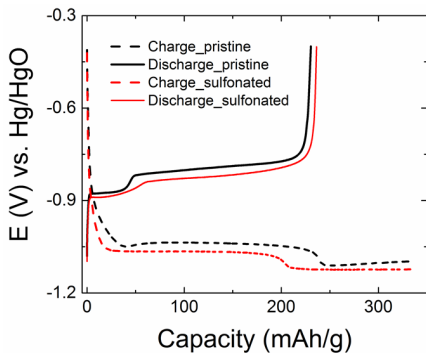

Casted electrodes on Ni foam in alkaline pouch cell

Hydrogen evolution at potentials below -1.2V

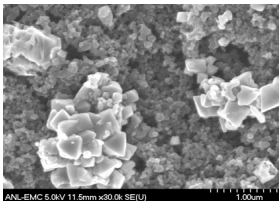

Fe₂O₃ cyclic voltammetry shows redox reactions of Fe in both pristine and sulfonated nanoparticles

Solid state performance

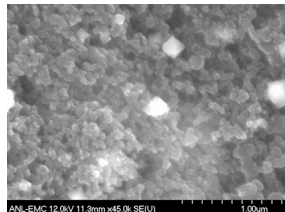

Performance of sulfonated nanoparticles very similar to pristine

Morphology of pristine electrode changes

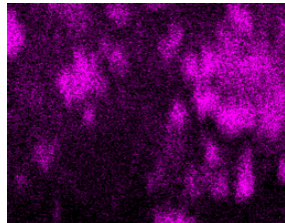

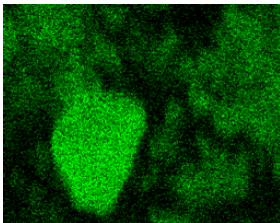

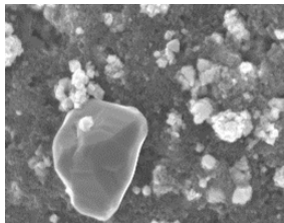

pristine

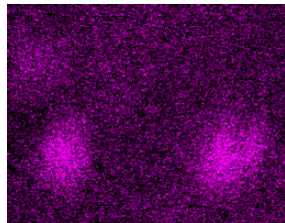

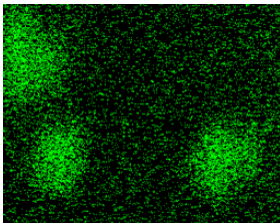

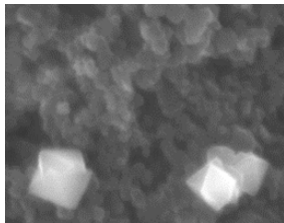

sulfonated

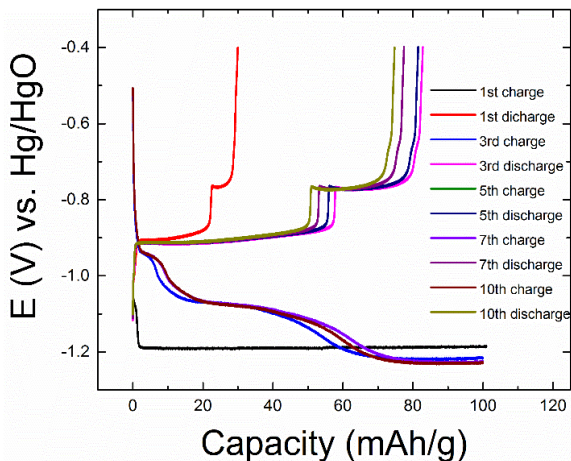

Fe₂O₃ post-cycling analysis

Pristine Fe₂O₃ electrodes show recrystallized Fe metal particles

Sulfonated Fe₂O₃ electrodes show only oxide particles

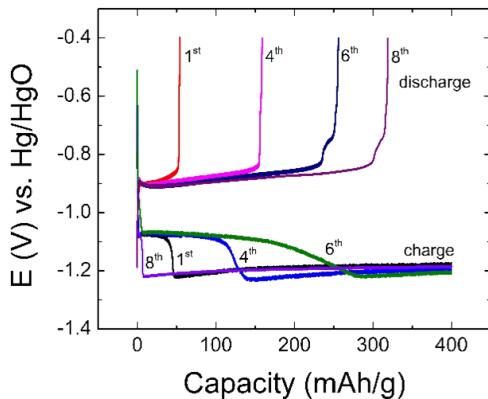

5% wt suspension of Fe₂O₃ nanoparticles in KOH/LiOH solution

Capacity increase with cycles indicates that it is limited by suboptimal current collector

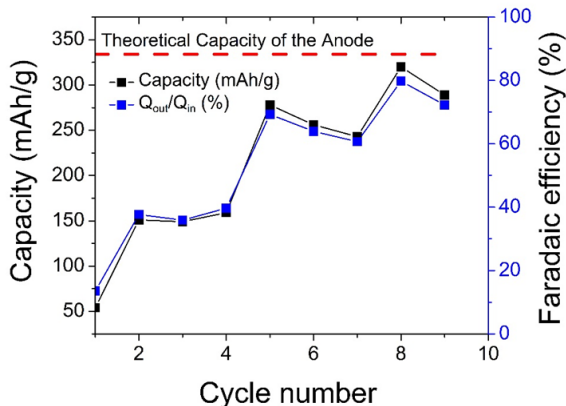

Need to move to flow-through current collector design

Pristine Fe_2O_3 NEF performance

5% suspension of
pristine Fe_2O_3 , over-
charged and discharged
at C/33 with improved
electrode

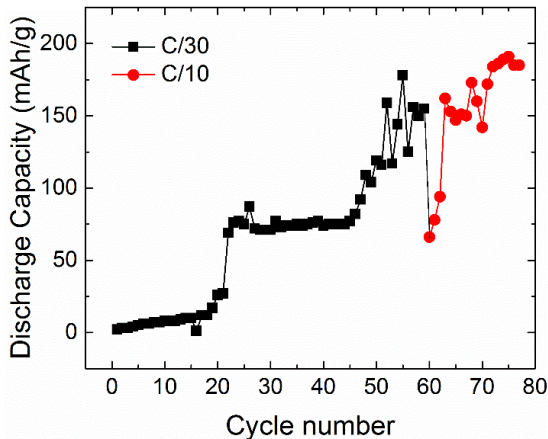

Pristine Fe_2O_3 NEF performance

5% suspension of pristine Fe_2O_3 , over-charged and discharged at C/33 with improved electrode

With repeated cycling, the performance of the NEF is increasing with a capacity of up to 300 mAh/g

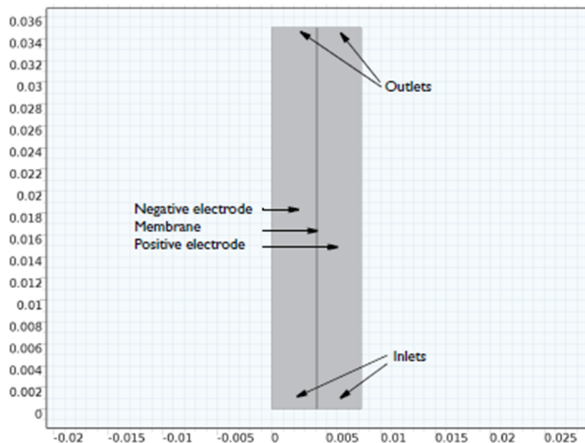

Sulfonated Fe_2O_3 NEF performance

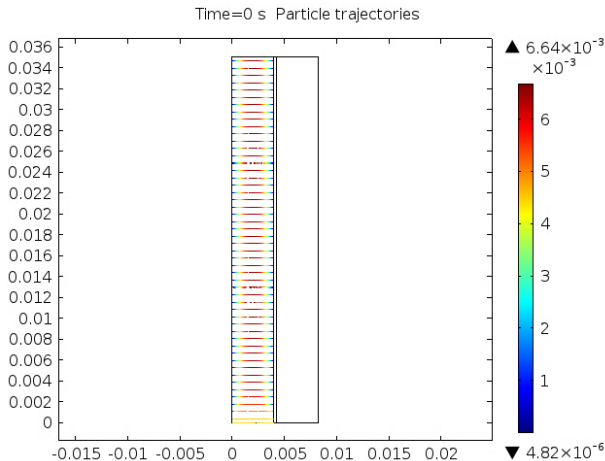

5% suspension of sulfonated Fe_2O_3 , over-charged and discharged at C/30 and C/10 with improved electrode

Capacity lower than pristine Fe_2O_3 but improving with training

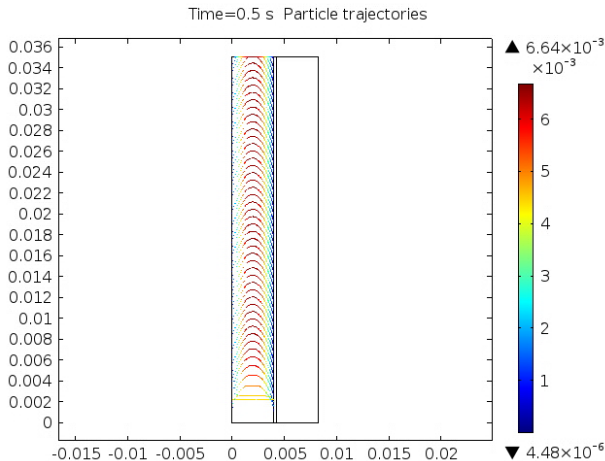

Surface treatment may be preventing conversion to metallic Fe, thus lower “capacity”

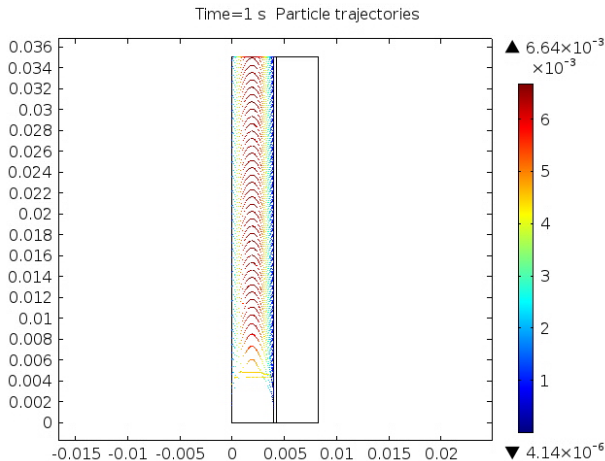

Initial model includes charged particle-particle interaction, interaction with electrode, and particle-fluid interaction

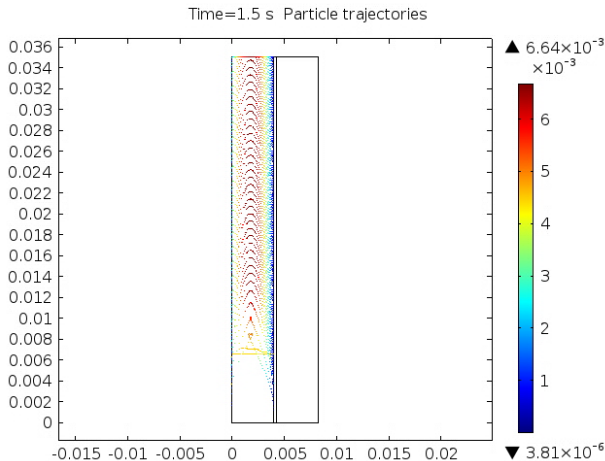

Initial model includes charged particle-particle interaction, interaction with electrode, and particle-fluid interaction

The EXAFS experiment

- Conceptually simple
- Transmission or fluorescence
- “Sees” amorphous phases & local structural distortions

The EXAFS equation

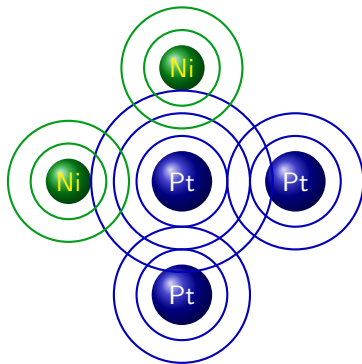

The EXAFS oscillations can be modelled and interpreted using a conceptually simple equation (the details are more subtle!)

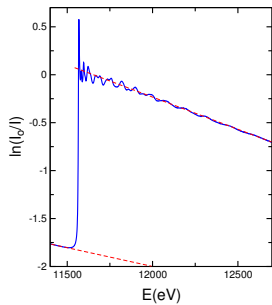

$$\chi(k) = \sum_j \frac{N_j S_0^2 f_j(k)}{k R_j^2} e^{-2k^2 \sigma_j^2} e^{-2R_j/\lambda(k)} \sin[2R_j + \delta_j(k)]$$

The sum could be over **shells** of atoms (Pt-Pt, Pt-Ni) or over **scattering paths** for the photo-electron.

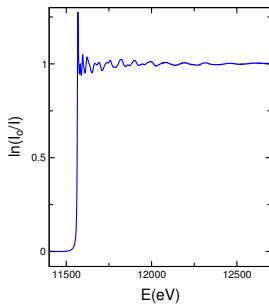

$f_j(k)$: scattering factor for the path
 $\lambda(k)$: photoelectron mean free path
 $\delta_j(k)$: phase shift for the j^{th} path

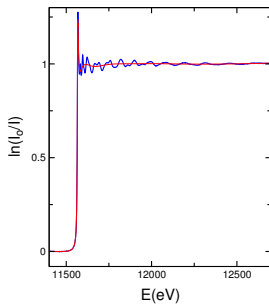

N_j : number of paths of type j
 R_j : half path length
 σ_j : path “disorder”

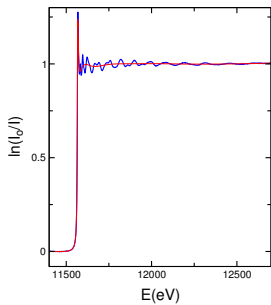

EXAFS analysis

take **Fourier Transform**
and fit with a structural
model

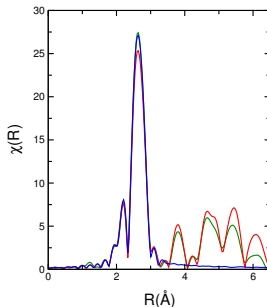

EXAFS analysis

remove background and
apply k-weighting

extract structural parameters for **first shell** or **more distant atoms** as appropriate

take **Fourier Transform**
and fit with a structural
model

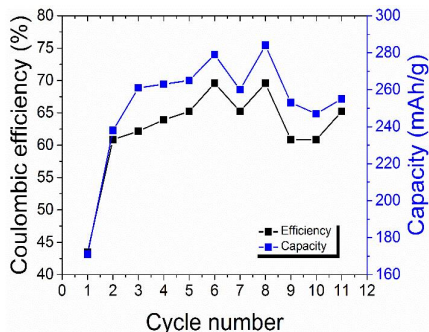

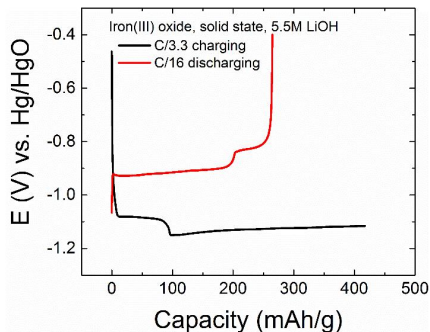

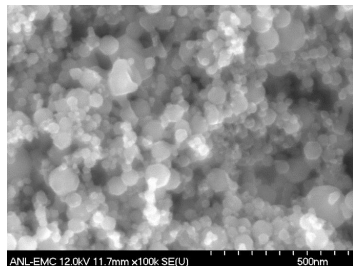

Fe₂O₃ *in situ* studies

Charging reaction: 335 mAh/g

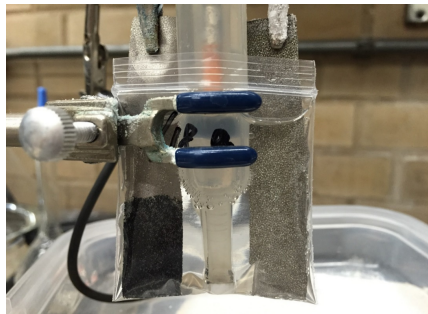

Over-charging reaction: 670 mAh/g

In situ Fe_2O_3 charging

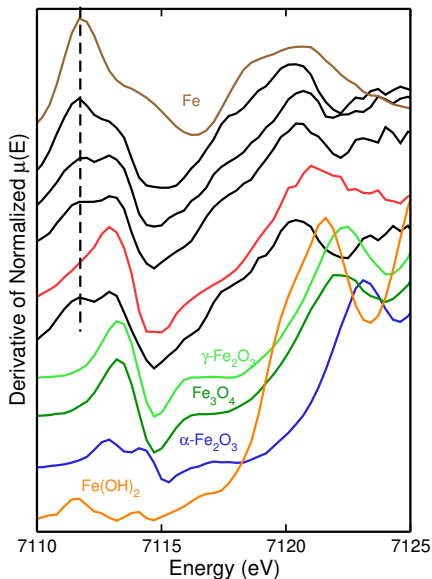

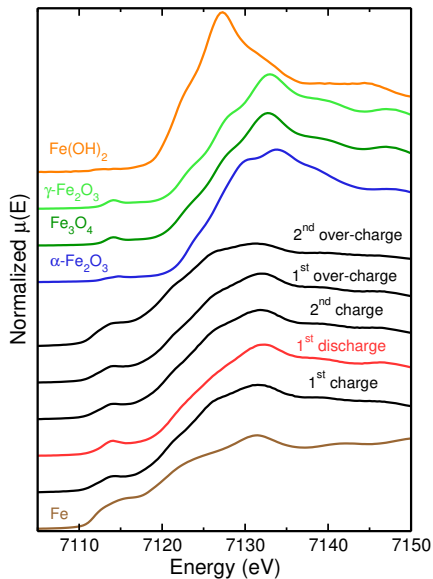

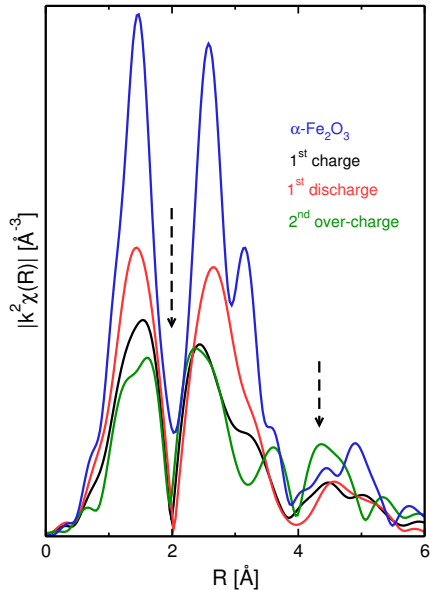

- Aqueous pouch cell
- Ni-mesh electrode
- MRCAT 10-BM beam line
- Fluorescence mode data acquisition
- ~45 min per data set

- Only take data at end of charge/discharge
- First & second charges to 335 mAh/g
- Discharges only produce 150 mAh/g
- Two over-charges to 1005 mAh/g

Fe₂O₃ XANES

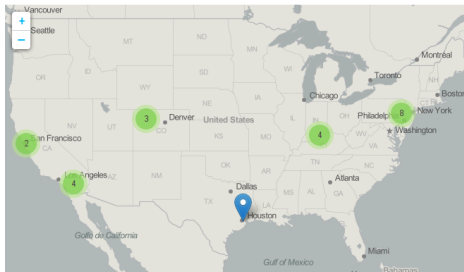

- Clear evidence of metallic Fe but no Fe(OH)₂ seen
- Discharge does not return electrode to α -Fe₂O₃
- Over-charge pushes system toward metallic Fe
- Fitting reveals mixture of Fe and/or Fe₃O₄/γ-Fe₂O₃ in all spectra.

	Fe ₃ O ₄	metallic Fe
1 st charge	85%	15%
1 st discharge	100%	
2 nd charge	83%	17%
1 st over-charge	82%	18%
2 nd over-charge	67%	33%

Initial funding: the RANGE program

Robust Affordable Next Generation Energy Storage Systems

Develop transformational electrochemical energy storage technologies for electric vehicles (EVs)

- provide greater EV driving range
- reduce overall weight of the vehicle
- maximize the overall energy stored in a vehicle
- enhance safety
- minimize manufacturing costs
- enable greater design flexibility for manufacturers

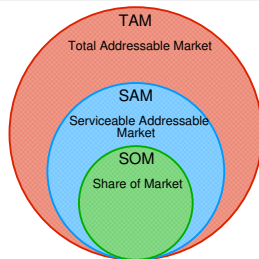

22 projects across the United States
